

COAL

Coal is found in Mississippian, Jurassic, Cretaceous and Tertiary non-marine sequences which underlie as much as 37 000 km² of the Yukon. The largest deposits and those with the greatest potential are located within the mid-Cretaceous to Eocene strata of the Bonnet Plume Basin of northeastern Yukon.

COAL

Coal also occurs within the Jura-Cretaceous sedimentary rocks in the Whitehorse Trough, which were formed in fan deltas which separated the emerging arc terrain from flyschoid environments within the trough. Some deposits occur in Cretaceous to Eocene basins along the Tintina Fault.

Coal occurrences also are documented in the southeast Yukon's Rock River Basin, a 50 km by 10 km graben or half-graben filled with Late Cretaceous to Eocene sedimentary rocks.

Significant efforts to develop the coal resources have taken place in the four areas listed below.

Division Mountain

The Division Mountain coal deposit is located 90 km northwest of Whitehorse, approximately 20 km west of the Klondike Highway and the 138 kV Southern Yukon electrical transmission grid. Cash Minerals has identified a deposit of 52.5 Mt of high-ash, low-

sulphur, high-volatile bituminous B. It occurs in seams of mineable thickness, and there is probable continuity along the strike for at least 15 km. Furthermore, there is considerable potential in the area to discover more coal.

Whitehorse Coal

Whitehorse Coal is located approximately 30 km southwest of Whitehorse, close to transportation routes and domestic markets. Seams of mineable thickness, 0.6 to 13 m, have been identified extending discontinuously for 12 km. The coal is a low-sulphur, moderate to high ash anthracite. Coal near the surface is highly oxidized.

Rock River

Coal is confined to an area approximately 10 by 50 km, and is mostly concealed by a mantle of clay, gravel and sand, locally up to 30 m thick. Based on five drill holes totalling 720 m, there appears to be approximately

Typical exposure of the coal-bearing Tanglefoot formation, east of Carmacks. (above) Discovery outcrop at the Division Mountain coal deposit which occurs in the upper Tanglefoot formation within the Whitehorse Trough.

60 Mt of coal within 80 m of the surface. It is classified lignite A to sub-bituminous C, with a thermal content of 3,720 kCal/kg. A gravity survey outlined anomalous areas indicating a potential for up to 1.5 Bt. The coal is amenable to surface mining at a ratio of approximately 2 to 1, waste to coal by volume.

Bonnet Plume

The Bonnet Plume Basin is located in the northern Yukon approximately 100 km to the east of the Dempster Highway. It contains the Yukon's

largest resources of coal, 660 Mt of high volatile bituminous C, in seams of mineable thickness. The coal is of low sulphur content and is potentially clean-burning. The coal is potentially suitable for conversion to clean gaseous or liquid fuels.

The following table, extracted from the document "Yukon Coal Potential," is a more detailed summary of the coal in the South Bonnet Plume Basin a mid-Cretaceous to Tertiary sedimentary basin which hosts the largest coal resources in Yukon.

South Bonnet Plume Basin coal

Location	Seam name	Average seam thickness (m)	Type (rank) of coal	Moisture content (%)	Ash content (%)	Volatile content (%)	Fixed carbon (%)	Sulphur content (%)	Calorific value (BTU/lb) (MJ/kg)		Resource-measured (million tonnes)*	Resource-indicated (million tonnes)*	Resource-inferred (million tonnes)*	Resource-total (million tonnes)*

‡Mineral resource-reserve category: resource and reserve figures have been compiled from a variety of historical data sources that in most cases predate the implementation of National Instrument 43-101. Therefore, only those figures indicated by an asterisk (*) comply with National Instrument 43-101.

Chert-pebble conglomerate, typical of the coal-bearing Jura-Cretaceous Tantalus Formation. Coal was mined from this formation at the Tantalus mine in Carmacks for use in mineral production at the Anvil zinc-lead mine.

Coal mining in 1992 by Nadahinni Mining on the Whiskey Lake deposit near Ross River. This coal was being mined from Cretaceous to Eocene conglomerates along the Tintina Fault. It was used for plant heating and concentrate drying at the Anvil Mine.
